
ImageCAS-X — request for the 160 paired re-annotations (inter-observer subset)

Hi Zulhilmi,

Thanks for your email. I am glad you liked our paper.

We had not planned to release the second set of annotations for the ImageCAS test set. The first set of annotations have been double checked by the senior analyst and any errors corrected. These labels act as the ground truth. The second set of annotations have not been checked, which this was intentional to get a better estimate of the inter-observer variability. I would rather not release the second set in case users got the wrongly considered them equal.

You may have also read in our paper: *"Furthermore, both annotators edited the same automatically generated centerlines and initialised their segmentations using a 3D U-Net which predicted the same boundaries for unedited centerlines, and therefore the DSC inter-observer variability should be considered the upper-bound of agreement."* As far as I am aware, all works that measure inter-observer variability of coronary measurements will also use some shared initial prediction generated automatically, which may limit its use in the kind of study you are suggesting.

Perhaps you could compare the predictions of CAS-Net or nnUNet to our official segmentations to get a distribution of predictions or a single scan. I think this would be valid, and I'd be happy to send you those.

Best of luck with your research - it sounds very interesting.
